Multi-purpose valve

The present invention relates to a multi-purpose valve for use as a therapeutic device. The multi-purpose valve according to the invention is designed for the treatment of chronic, venous insufficiency secondary to primary valvular incompetence or post-thrombotic syndrome. Furthermore, the device can act
5 as an inexpensive alternative to artificial heart valves which are in use and as a sphincter at extravascular locations such as the urethra and the pylorus.

Venous valves are crucial for normal blood flow in the lower extremities. Damage to these structures is a common result of thrombosis, leading to the
10 development of post-thrombotic syndrome, a common, chronic and often disabling disease.

Surgical reconstruction of venous valves is a technically demanding procedure and therefore has achieved only limited acceptance in clinical practice. Thus there is a clear need for an artificial valve which can be
15 implanted in the veins.

In addition to this, there is a need for artificial heart valves which can be implanted through the skin, and sphincteric devices which can be placed in the urethra and the pylorus.

Some bioprosthetic valves have been developed for use as venous valves
20 (e.g. US-A-5 500 014) but none of them has been found suitable for clinical application. These devices consist substantially of a rigid metal ring covered by a biocompatible polymer. Heart valve flaps from pigs or flaps designed from bovine pericardium which are attached by means of glutaraldehyde are secured by sutures to the metal ring. The main advantage of these devices is
25 that they are based on a concept which has been tried and tested in the heart. However, this advantage must be weighed against the risk which is involved in using animal tissue. Bioprosthetic valves, moreover, have a limited life due to the degenerative changes which inevitably follow implantation. The bioprosthetic valves have only been tested as venous valves in vitro or in the
30 largest central veins in non-primate mammals. Thus their real thrombogenic potential is still unknown.

Another known valve is a metallic flap disc valve (developed at Millard Fillmore Hospital by Taheri et al.). This valve has been shown to be unsatisfactory.

5 These and other problems related to the known devices are solved by means of the multi-purpose valve according to the invention. This valve is characterized in that it consists of a band of a thermodynamic (or temperature-sensitive) metal alloy with shape memory, with a memorised shape and a transition temperature which lies within the range of normal body temperature for a mammal, with the result that the band has a linear
10 shape below the transition temperature and assumes the memorised shape above the transition temperature, the memorised shape being a conical spiral.

In a further preferred embodiment of the invention, the band is provided on one surface with flexible, highly magnetic strips and on the opposite side with ferromagnetic strips. This feature permits prostheses to be manufactured
15 with different opening pressures simply by altering the pole strength of the magnetic strips.

The valve according to the invention is designed by winding a thin, narrow band of a thermodynamic metal alloy with shape memory (e.g. Nitinol) round a mould with a suitable shape and heat treating it. The alloy is characterized
20 by long-term stability under cyclic loading, and its transition temperature lies below the normal body temperature. All metallic surfaces are preferably covered with a biocompatible, bistable, non-thrombogenic polymer layer. Below the transition temperature range, the thermodynamic metal is in a martensitic state and the device has a linear shape. Above the martensitic
25 transition temperature range the metal band is transformed to austenitic state, thereby recovering the memorised shape which it received during heat treatment.

Another important feature of the invention is that it permits transcatheter implantation through the skin, on account of the band's linear shape before it
30 reaches normal body temperature. The band with its linear shape can easily be inserted in the body and subsequently, when the transition temperature is reached, it will assume a valve shape.

The valve according to the invention can be manufactured from freely available materials, and it does not include animal tissue of any type. This

eliminates the risk of transferring zoonotic infections and of causing undesirable immune reactions.

5 In a preferred embodiment the whole device is covered with a biocompatible, non-thrombogenic, biostable polymer (e.g. low-molecular-weight dimer of parachloroxylylene (parylene), thus eliminating the risk of chemical interaction between the substrate and the blood. Human cells proliferate rapidly and easily on the parylene-coated surface to produce thin adhesion layers of morphologically normal tissue. Thus rapid endothelium cover of the prosthesis according to the invention can be predicted, thereby minimising
10 the risk of *de novo* thrombosis.

The invention will now be described by means of an illustrating and non-limiting embodiment, which is illustrated in the following drawings, in which:

15 figs. 1 and 2 illustrate the valve according to the invention in a state below transition temperature;

fig. 3 illustrates the valve according to the invention in a state above the transition temperature and closed;

fig. 4 illustrates the valve according to the invention in a state above transition temperature and open;

20 figs. 5a and 5b illustrate use of the valve according to the invention in leg veins; and

fig. 6 illustrates use of a valve according to the invention as an aortic valve.

25 Fig. 1 illustrates the valve according to the invention in a state below the transition temperature range of the thermodynamic material. This figure illustrates what will be the valve's outer surface when the temperature has increased above the transition temperature range. As already mentioned, in "the low temperature state" the valve consists of a thin, narrow band 1 of a thermodynamic metal alloy with shape memory (e.g. an echiatomic nickel-titanium, intermetallic alloy such as nitinol), characterized by long-term
30 stability under cyclic loading. The valve's outer surface is provided with highly magnetic strips 2 with a high degree of remanence.

Fig. 2 illustrates what will form the inner surface of the valve according to the invention, in a state below the transition temperature. On this side the band 1 is provided with ferromagnetic strips 3.

5 The magnetic strips on both sides of the band have a direct influence on the valve's pressure gradient for opening and closing by providing magnetic attraction forces between helical coils located in the immediate vicinity of one another.

Fig. 3 illustrates the valve above the transition temperature range for the thermodynamic metal and closed. The valve's body 5 consists of a plurality
10 of successive coils which partly overlap one another, thereby forming a hollow cone. The last coil or "connecting part" 6 is a single coil which is located in a plane at right angles to the body's 5 longitudinal axis and continuous with the part 5.

Fig. 4 illustrates the valve above the transition temperature range for the
15 thermodynamic metal and open. The "nose" or the top 4 of the valve comprises a plurality of successive coils which overlap one another completely, forming a flat spiral which closes the cone, and which is continuous with the valve's body 5.

The main function of the valve according to the invention, both in the vein
20 (figs. 5a, 5b) and heart (fig. 6) embodiments is to ensure one-way flow, the temporal pattern of which varies according to the anatomical location. In the leg veins the preferred direction for blood flow is towards the heart, and the temporal pattern is substantially continuous with occasional interruptions. It is therefore important for an artificial venous valve to remain open as long as
25 there is a pressure gradient in the direction of the heart, and to close quickly when this gradient is reversed.

In the venous embodiment (figs. 5a, 5b), the adjacent strips in the multi-purpose valve according to the invention will not overlap one another (i.e. they will remain open) in the absence of external axial forces. Axial forces
30 acting along the vector between the connecting part and the "nose" will further distract adjacent turns of the spiral. Since the valve will be placed with its "nose" facing the heart, it will remain open in the presence of a pressure gradient in the direction of the heart (vein \rightarrow heart), (fig. 5a, $P(p) > P(c)$, where $P(p)$ = intraluminal pressure peripheral to the valve, $P(c)$ =

intraluminal pressure central to the valve). When the direction of the pressure gradient is reversed (heart → vein), as is the case when a person rises, axial forces oriented along the "nose to connecting part" vector will act on the valve, laying each coil overlappingly on its immediately underlying neighbour, thereby causing the valve to be closed (fig. 5b). This process is facilitated by the attractive force exerted by the magnetic strips on the adjacent ferromagnetic counterparts.

In contrast to this, in heart (fig. 6) and extravascular embodiments, the valve will remain closed in the absence of external axial forces, since in these anatomical locations the normal flow temporal pattern are invariably intermittent. However, in the same way as for the veins, the valve's physical state (open/closed) at a given point of time will be determined by the internal pressure gradients. Fig. 6 illustrates the multi-purpose valve according to the invention in the aorta location. In this case the pressure gradient is the difference between left ventricular pressure ($P(LV)$) and aortic pressure ($P(A)$).

In a preferred embodiment of the invention (not shown) which is suitable for surgical use, the system for affixing the valve comprises a series of holes which are drilled in the connecting part through which sutures can be passed.

In a second preferred embodiment of the invention (not shown), which is suitable for transcatheter use, the system for affixing the valve comprises a series of barbs attached to the connecting part's outer surface or an expandable vascular stent.

The multi-purpose valve according to the invention is entirely free of joints. The possibility of structural defects during long-term use will thus be much smaller than, e.g., for the bioprosthetic valve. In contrast to the latter, the design of the valve according to the invention is suitable for automated manufacture, thus simplifying the manufacturing process.

The possibility of transcatheter implantation through the skin is one of the greatest advantages of the valve according to the invention compared to all the artificial heart valves in use. The same applies in comparison to applications as a urinary sphincter.

The valve according to the invention therefore opens the possibility of valve replacement even for patients who will not be able to withstand major surgery.

- 5 In contrast to the artificial urethra sphincters which are in use, the valve according to the invention resembles the ordinary urethra sphincter in the manner that its function will be modulated by the bladder pressure.

PATENT CLAIMS

1. A multi-purpose valve for use as a therapeutic device,
characterized in that the valve consists of a band of a thermodynamic metal
alloy with shape memory, with a memorised shape and transition temperature
5 in the range for the normal body temperature of a mammal, with the result
that the band has a linear shape below the transition temperature and assumes
the memorised shape above the transition temperature, the memorised shape
being a conical spiral.
2. A multi-purpose valve according to claim 1,
10 characterized in that the thermodynamic metal alloy with shape memory is
Nitinol.
3. A multi-purpose valve according to one of the claims 1-2,
characterized in that the band is provided on one surface with flexible
magnetic strips of strong magnetic force and on the other surface with
15 ferromagnetic strips.
4. A multi-purpose valve according to one of the claims 1-3,
characterized in that the band is covered with a non-thrombogenic, biostable
polymer, e.g. parylene.
